AI Learning Content Studio

A small prototype exploring how AI could help turn training material into useful learning resources.

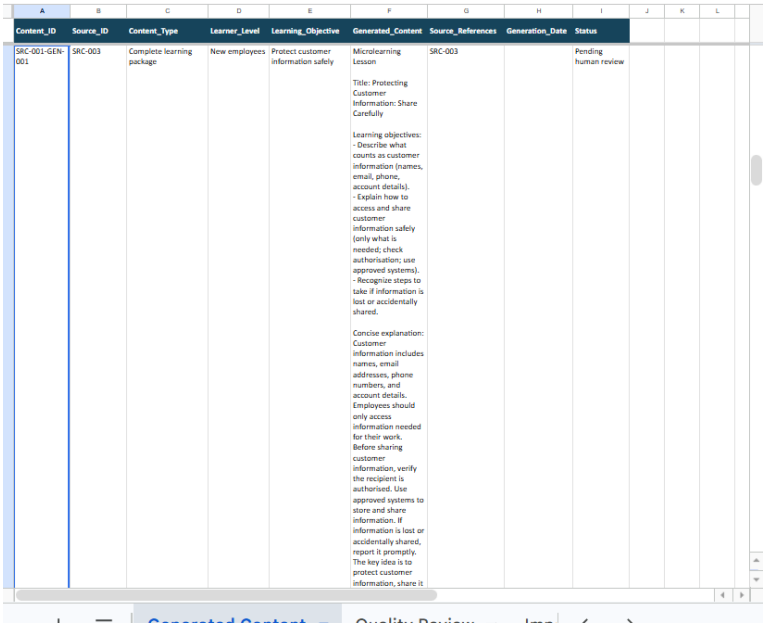

Created by	Uchenna Jennifer Ibeh
Version	1.0 – Initial prototype
Tools used	Make.com, Google Sheets and Make AI Toolkit

What I wanted to try

I wanted to see whether I could use a simple AI workflow to take a training document and turn it into a few different learning materials, without having to create each one from scratch. I built this as a practical experiment using a sample topic: protecting customer information.

The idea is straightforward: add source material to a spreadsheet, let AI draft the learning content, save the result, and have a person check it before anyone uses it.

The workflow

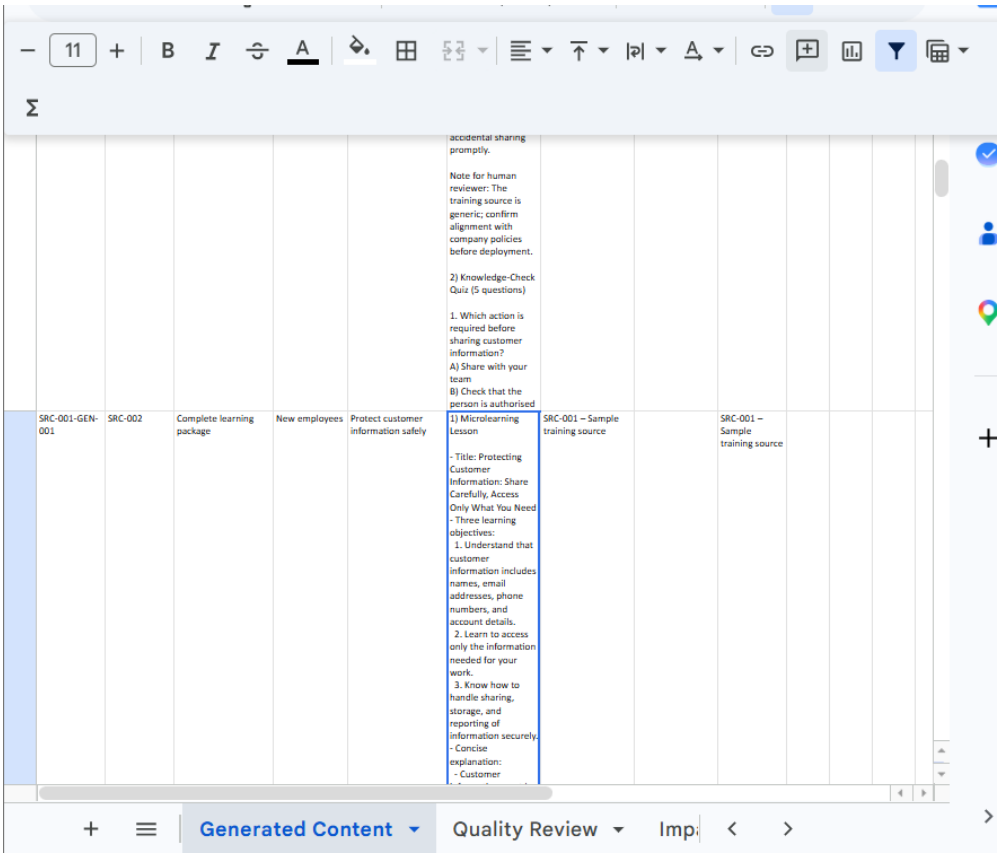

Content_ID	Source_ID	Content_Type	Learner_Level	Learning_Objective	Generated_Content	Source_References	Generation_Date	Status
SRC-001-GEN-001	SRC-003	Complete learning package	New employees	Protect customer information safely	Microlearning Lesson Title: Protecting Customer Information: Share Carefully Learning objectives: - Describe what counts as customer information (names, email, phone, account details). - Explain how to access and share customer information safely (only what is needed; check authorisation; use approved systems). - Recognize steps to take if information is lost or accidentally shared. Concise explanation: Customer information includes names, email addresses, phone numbers, and account details. Employees should only access information needed for their work. Before sharing customer information, verify the recipient is authorised. Use approved systems to store and share information. If information is lost or accidentally shared, report it promptly. The key idea is to protect customer information, share it	SRC-003		Pending human review

The Make.com scenario: Google Sheets → Make AI Toolkit → Google Sheets.

1. From source material to learning content

The first Google Sheets tab holds the source material and basic details, such as the intended audience and topic. Make.com watches for a new row and passes the training text to the AI prompt. The response is then added to the Generated Content tab.

For this example, the AI drafted a short microlearning lesson, a five-question knowledge check and a facilitator guide. The generated lesson includes learning objectives, a short explanation, practical examples and key takeaways.

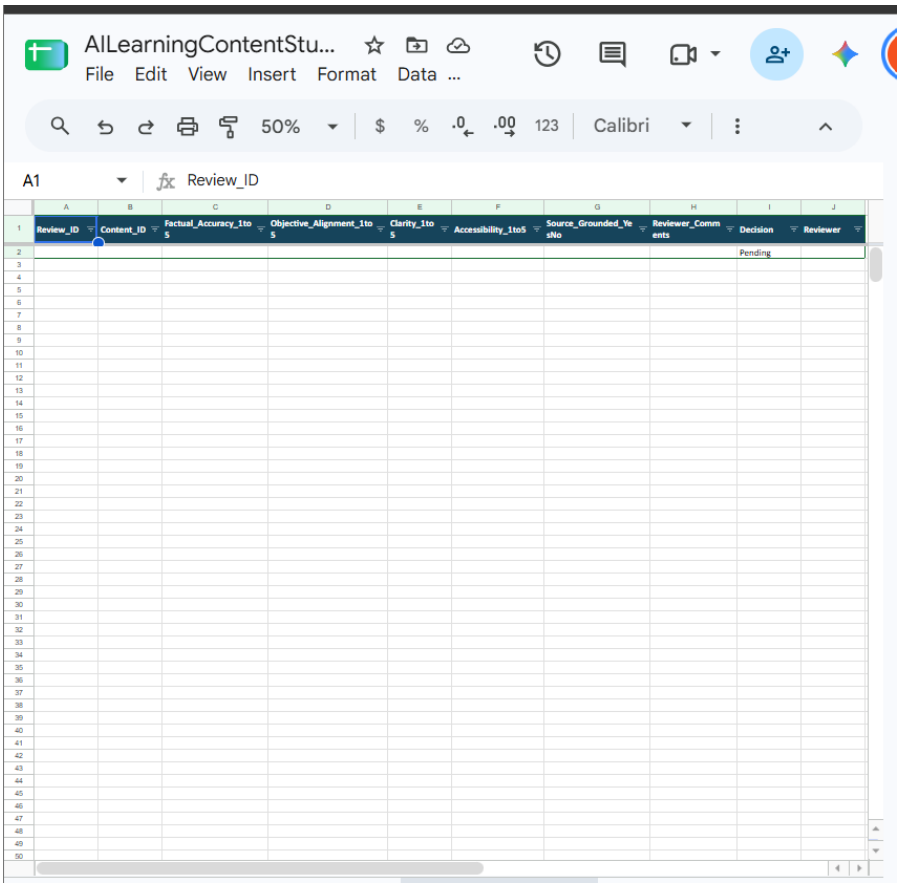

Generated content saved in the Google Sheets tracker.

2. Keeping a person in the process

I added a Quality Review tab because generated content should not go straight to learners without being checked. The review fields cover accuracy, alignment with the learning objectives, clarity, accessibility and whether the content is supported by the source.

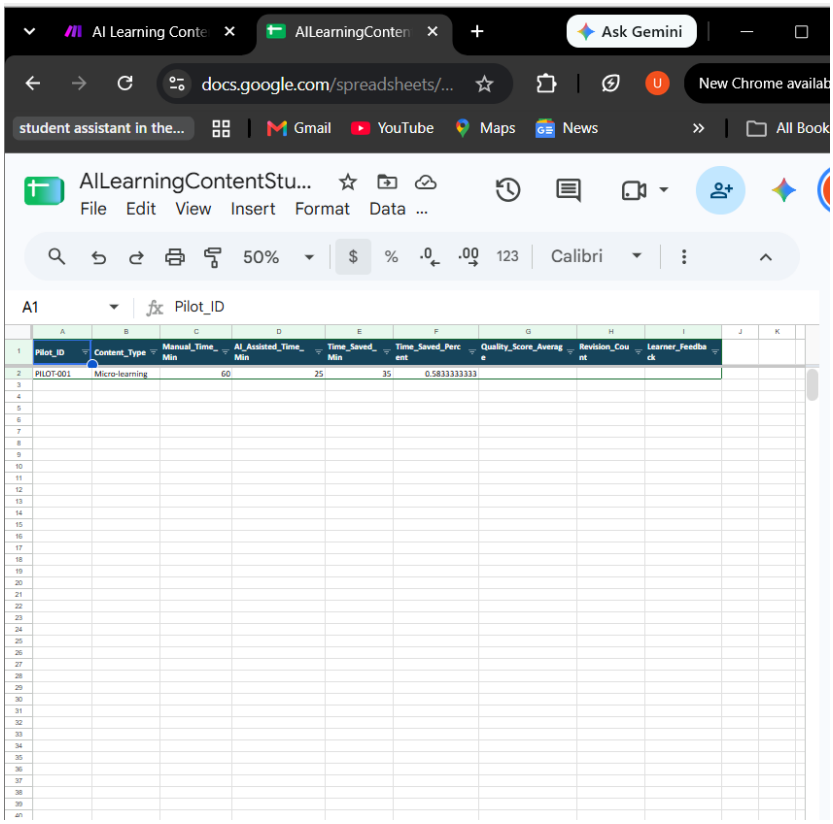

For this demonstration, I entered a sample review and marked the material as approved for demo only. I also noted that it would need to be checked against approved company policies before being used at work.

Quality Review tracker with the sample reviewer comments.

3. Thinking about impact

The final tab is there to record how long content creation takes, how much time an AI-assisted draft takes, and whether the result needs revisions. It also has space for quality scores and learner feedback.

Impact Metrics tracker. The time figures shown are examples for the demonstration, not measured results.

What I learned and what I would do next

Building this gave me hands-on experience connecting a spreadsheet trigger, an AI prompt and an automated output. It also helped me think beyond generating text: the content needs to be relevant to the learner, grounded in the source and reviewed by a person.

If I developed it further, I would:

- Try it with approved training materials and feedback from instructional designers.
- Improve the prompt and add checks to make sure generated content stays close to the source.
- Explore other outputs, such as localised content and refreshed learning materials.
- Test the content with learners and collect feedback on usefulness and clarity.
- Compare actual creation time and quality with the existing process.

A note on the demo

This is an early proof of concept using generic sample material. It has not been tested with real learners or deployed in an organisation. The tracker shows an example comparison of 60 minutes for manual creation and 25 minutes for AI-assisted creation (35 minutes, or 58.3%, saved). These figures are illustrative only; I have not measured a real time saving. The sample content also needs to be checked against an organisation's own policies before use.
